

Module 1: N+ Network Fundamentals and building networks

Introduction to Networks

Task 1:

Task 2:

Device	Network Type
Smartphone	WAN (mobile data) and LAN (when on WiFi)
WiFi Router	LAN (connects devices at home) and WAN (links to ISP)
Smart TV	LAN
Laptop	LAN/WAN
Smartwatch	PAN (Bluetooth link to phone)

Task 3:

The **Internet** is a public, global network anyone can access - it connects billions of devices worldwide with no single owner.

An **intranet** is a private network restricted to one organization, accessible only to its members.

Example: your college's WiFi login portal that only lets students and staff sign in with a college ID, and gives access to internal resources like the library catalog, attendance system, or exam results - that's an intranet. The moment you open a browser and visit YouTube or Google through that same WiFi, you're using the Internet. Same physical WiFi connection, but two different "networks" depending on what you're reaching: internal college resources (intranet) vs. the open web (Internet).

Task 4:

Data journey — Zomato search example

When you type a restaurant name and hit search on Zomato: your phone converts the query into a small data packet and sends it over WiFi or mobile data (WAN) to your router, which forwards it through your ISP onto the internet. The request travels across multiple routers until it reaches Zomato's server, which searches its database for matching restaurants. The server packages the results and sends them back along the same path — Internet → ISP → router → phone — and your app renders the list on screen, typically within a second or two.
